Operating Systems CSCI 3150

Lecture 7: Synchronization (III) -- Semaphores

Hong Xu

https://github.com/henryhxu/CSCI3150

Semaphore

- It provides
 - Mutex
 - And atomic counters
- Two operations:
 - ◆ P(semaphore), Wait(): after the Dutch word for test
 - V(semaphore), signal(), post(): after the Dutch word for increment
- Probably the most unintuitive names you encounter in this course
 - You have Edsger W. Dijkstra to thank to

Semaphore: A definition

- An object with an integer value
 - We can manipulate with two routines; sem wait() and sem post().
 - Initialization

```
1 #include <semaphore.h>
2 sem_t s;
3 sem_init(&s, 0, 1); // initialize s to the value 1
```

- Declare a semaphore s and initialize it to the value 1
- The second argument, 0, indicates that the semaphore is <u>shared</u> between *threads in the same process*.

Semaphore: Interact with semaphore

sem_wait()

```
1 int sem_wait(sem_t *s) {
2         decrement the value of semaphore s by one
3         wait if value of semaphore s is negative
4 }
```

- If the value of the semaphore was *one* or *higher* when called sem_wait(), **return right away**.
- It will cause the caller to <u>suspend execution</u> waiting for a subsequent post.
- When negative, the value of the semaphore is equal to the number of waiting threads.

Semaphore: Interact with semaphore (Cont.)

sem_post()

```
int sem_post(sem_t *s) {
    increment the value of semaphore s by one
    if there are one or more threads waiting, wake one
}
```

- Simply increments the value of the semaphore.
- If there is a thread waiting to be woken, wakes one of them up.

time	Τ,	٦,	د ۲	14	Semaphone S
to					0
t,	Sem-wait(s),				- 1
t	Se	in-wart(5);		-2
t ₃			Sem-wart	5) >	-3
ty				Sem-post(s)	<u>-)</u>

Binary Semaphores (Locks)

What should x be?

• The initial value should be **1**.

```
1   sem_t m;
2   sem_init(&m, 0, X); // initialize semaphore to X; what should X be?
3
4   sem_wait(&m);
5   //critical section here
6   sem_post(&m);
```

Value of Semaphore	Thread 0	Thread 1
1		
1	<pre>call sema_wait()</pre>	
0	<pre>sem_wait() returns</pre>	
0	(crit sect)	
0	<pre>call sem_post()</pre>	
1	sem_post() returns	

Thread Trace: Two Threads Using A Semaphore

Value	Thread 0	State	Thread 1	State
1		Running		Ready
1	call sem_wait()	Running		Ready
0	sem_wait() returns	Running		Ready
0	(crit set: begin)	Running		Ready
0	Interrupt; Switch → T1	Ready		Running
0		Ready	call sem_wait()	Running
-1		Ready	decrement sem	Running
-1		Ready	(sem < 0)→sleep	sleeping
-1		Running	Switch → TO	sleeping
-1	(crit sect: end)	Running		sleeping
-1	call sem_post()	Running		sleeping
0	increment sem	Running		sleeping
0	wait(T1)	Running		Ready
0	sem_post() returns	Running		Ready
0	Interrupt; Switch → T1	Ready		Running
0		Ready	sem_wait() retruns	Running
0		Ready	(crit sect)	Running
0		Ready	call sem_post()	Running
1		Ready	sem_post() returns	Running

Semaphores As Condition Variables

```
sem t s;
    void *
    child(void *arg) {
        printf("child\n");
         sem post(&s); // signal here: child is done
6
        return NULL;
9
10
     int
11
     main(int argc, char *argv[]) {
12
         sem init(&s, 0, X); // what should X be?
        printf("parent: begin\n");
13
14
        pthread t c;
15
         pthread create(c, NULL, child, NULL);
16
         sem wait(&s); // wait here for child
17
        printf("parent: end\n");
18
        return 0;
19
```

A Parent Waiting For Its Child

parent: end The execution result

parent: begin

child

- What should x be?
 - The value of semaphore should be set to is **0**.

Thread Trace: Parent Waiting For Child (Case 1)

■ The parent call sem_wait() before the child has called sem_post().

Value	Parent	State	Child	State
0	Create(Child)	Running	(Child exists; is runnable)	Ready
0	call sem_wait()	Running		Ready
-1	decrement sem	Running		Ready
-1	(sem < 0)→sleep	sleeping		Ready
-1	Switch→Child	sleeping	child runs	Running
-1		sleeping	call sem_post()	Running
0		sleeping	increment sem	Running
0		Ready	wake(Parent)	Running
0		Ready	sem_post() returns	Running
0		Ready	Interrupt; Switch→Parent	Ready
0	sem_wait() retruns	Running		Ready

Thread Trace: Parent Waiting For Child (Case 2)

The child runs to completion before the parent call sem_wait().

Value	Parent	State	Child	State
0	Create(Child)	Running	(Child exists; is runnable)	Ready
0	Interrupt; switch→Child	Ready	child runs	Running
0		Ready	call sem_post()	Running
1		Ready	increment sem	Running
1		Ready	wake (nobody)	Running
1		Ready	sem_post() returns	Running
1	parent runs	Running	Interrupt; Switch→Parent	Ready
1	call sem_wait()	Running		Ready
0	decrement sem	Running		Ready
0	(sem<0)→awake	Running		Ready
0	sem_wait() retruns	Running		Ready

The Producer/Consumer (Bounded-Buffer) Problem

- Producer: put() interface
 - Wait for a buffer to become empty in order to put data into it.
- **□ Consumer**: get() interface
 - Wait for a buffer to become *filled* before using it.

The Producer/Consumer (Bounded-Buffer) Problem

```
sem t empty;
    sem t full;
    void *producer(void *arg) {
       int i;
6
       for (i = 0; i < loops; i++) {</pre>
                                 // line P1
               sem wait(&empty);
               put(i);
                                       // line P2
                                       // line P3
9
               sem post(&full);
10
11
12
13
    void *consumer(void *arg) {
       int i, tmp = 0;
14
15
       while (tmp != -1) {
16
               sem wait(&full);
                              // line C1
17
               tmp = qet();
                                       // line C2
18
               19
               printf("%d\n", tmp);
20
21
22
```

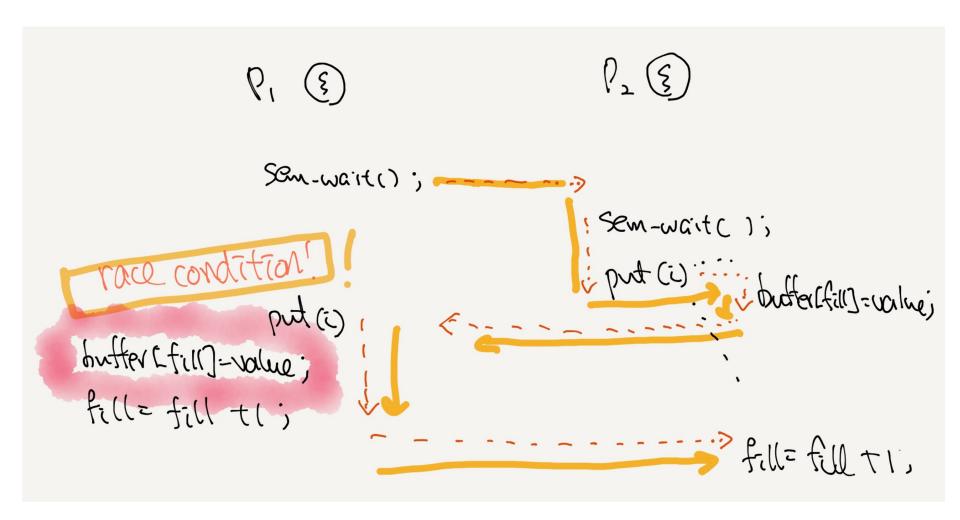

First Attempt: Adding the Full and Empty Conditions

The Producer/Consumer (Bounded-Buffer) Problem

First Attempt: Adding the Full and Empty Conditions (Cont.)

- Imagine that MAX is greater than 1
 - If there are multiple producers, race condition can happen.
 - o It means that the old data there is overwritten.

- We've forgotten here is mutual exclusion.
 - The filling of a buffer and incrementing of the index into the buffer is a critical section.

A Solution: Adding Mutual Exclusion

```
sem t empty;
  sem t full;
  sem t mutex;
4
  void *producer(void *arg) {
    int i;
    for (i = 0; i < loops; i++) {</pre>
         put(i);
                      // line p2
10
         sem post(&full); // line p3
11
12
         13
14
15
```

Adding Mutual Exclusion (Incorrectly)

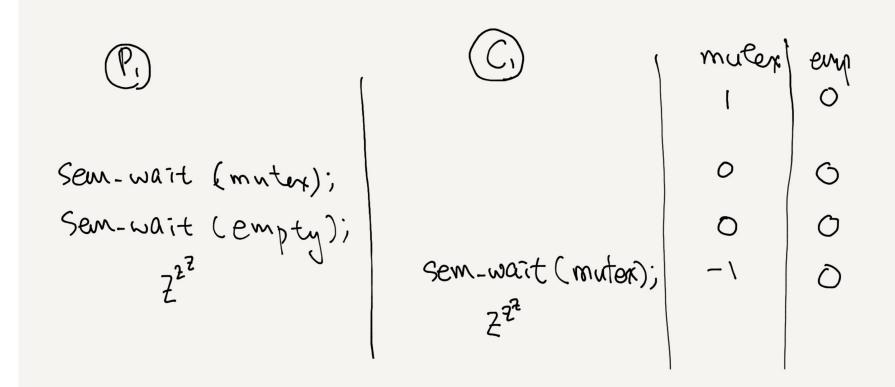

A Solution: Adding Mutual Exclusion

```
void *consumer(void *arg) {
16
17
       int i;
18
       for (i = 0; i < loops; i++) {</pre>
19
              sem wait(&mutex);
                                // line c0 (NEW LINE)
20
              sem wait(&full);
                                 // line c1
                                // line c2
21
              int tmp = get();
22
              23
              sem post(&mutex);
                                // line c4 (NEW LINE)
24
              printf("%d\n", tmp);
25
26
```

Adding Mutual Exclusion (Incorrectly)

A Solution: Adding Mutual Exclusion (Cont.)

- Imagine two thread: one producer and one consumer.
 - The consumer acquire the mutex (line c0).
 - The consumer **calls** sem wait() on the full semaphore (line c1).
 - The consumer is **blocked** and **yield** the CPU.
 - The consumer still holds the mutex!
 - The producer calls sem wait() on the binary mutex semaphore (line p0).
 - The producer is now **stuck** waiting too. a classic deadlock.

A Working Solution

```
sem t empty;
   sem t full;
   sem t mutex;
4
   void *producer(void *arg) {
       int i;
6
       for (i = 0; i < loops; i++) {</pre>
               9
               sem wait(&mutex); // line p1.5 (MOVED MUTEX HERE...)
10
               put(i);
                                     // line p2
               sem post(&mutex); // line p2.5 (... AND HERE)
11
               sem post(&full); // line p3
12
13
14
15
```

Adding Mutual Exclusion (Correctly)

A Working Solution

```
16
    void *consumer(void *arg) {
17
       int i;
18
       for (i = 0; i < loops; i++) {
19
              20
              sem wait(&mutex); // line c1.5 (MOVED MUTEX HERE...)
21
              int tmp = get(); // line c2
              sem post(&mutex); // line c2.5 (... AND HERE)
2.2
23
              24
              printf("%d\n", tmp);
25
26
27
28
   int main(int argc, char *argv[]) {
29
       // ...
30
       sem init(&empty, 0, MAX); // MAX buffers are empty to begin with ...
31
       sem init(&full, 0, 0); // ... and 0 are full
       sem init(&mutex, 0, 1); // mutex=1 because it is a lock
32
33
       // ...
34
35
```

Adding Mutual Exclusion (Correctly)

Reader-Writer Locks

Imagine a number of concurrent list operations, including inserts and simple lookups.

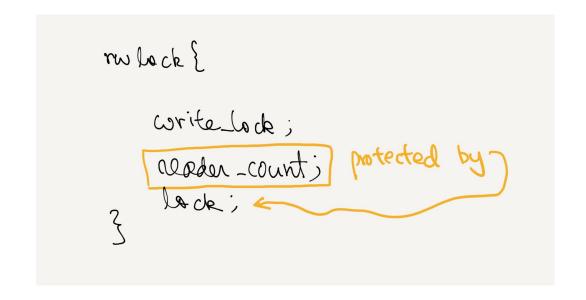

• insert:

- Change the state of the list
- A traditional <u>critical section</u> makes sense.

lookup:

- Simply *read* the data structure.
- As long as we can guarantee that no insert is on-going, we can allow many lookups to proceed concurrently.

This special type of lock is known as a reader-write lock.

A Reader-Writer Locks

- Only a single writer can acquire the lock.
- Once a reader has acquired a read lock,
 - More readers will be allowed to acquire the read lock too.
 - A writer will have to wait until all readers are finished.

```
1. void rwlock_init(rwlock_t *rw) {
2.    rw->readers = 0;
3.    sem_init(&rw->lock, 0, 1);
4.    sem_init(&rw->writelock, 0, 1);
5. }
```

A Reader-Writer Locks

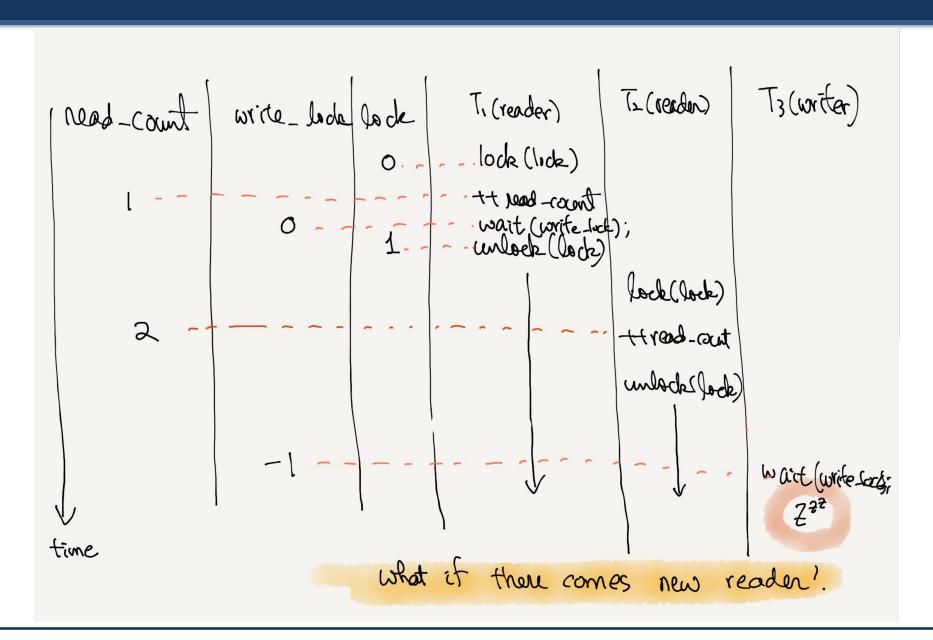

```
1. void rwlock_acquire_readlock(rwlock_t *rw) {
2.     sem_wait(&rw->lock);
3.     rw->readers++;
4.     if (rw->readers == 1)
5.         sem_wait(&rw->writelock); // first reader acquires writelock
6.     sem_post(&rw->lock);
7. }
```

```
1. void rwlock_release_readlock(rwlock_t *rw) {
2.    sem_wait(&rw->lock);
3.    rw->readers--;
4.    if (rw->readers == 0)
5.         sem_post(&rw->writelock); // last reader releases writelock
6.    sem_post(&rw->lock);
7. }
```

A Reader-Writer Locks (Cont.)

```
1. void rwlock_acquire_writelock(rwlock_t *rw) {
2.    sem_wait(&rw->writelock);
3. }
```

```
1. void rwlock_release_writelock(rwlock_t *rw) {
2.    sem_post(&rw->writelock);
3. }
```

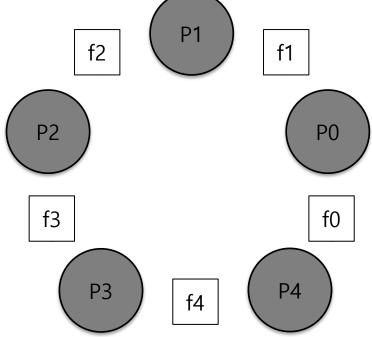

A Reader-Writer Locks (Cont.)

- The reader-writer locks have fairness problem.
 - It would be relatively easy for reader to starve writer.
 - How to <u>prevent</u> more readers from entering the lock once a writer is waiting?
 - It's called a "write-perferring RW lock"

The Dining Philosophers

- Assume there are five "philosophers" sitting around a table.
 - Between each pair of philosophers is <u>a single fork</u> (five total).
 - The philosophers each have times where they **think**, and don't need any forks, and times where they **eat**.
 - In order to *eat*, a philosopher needs two forks, both the one on their *left* and the one on their *right*.

The contention for these forks.

The Dining Philosophers (Cont.)

- Key challenge
 - There is no deadlock.
 - No philosopher starves and never gets to eat.
 - Concurrency is high.

```
while (1) {
         think();
         getforks();
         eat();
         putforks();
}
```

Basic loop of each philosopher

```
// helper functions
int left(int p) { return p; }

int right(int p) {
    return (p + 1) % 5;
}
```

Helper functions (Downey's solutions)

- Philosopher p wishes to refer to the for on their left \rightarrow call left(p).
- Philosopher p wishes to refer to the for on their right → call right (p).

The Dining Philosophers (Cont.)

We need some semaphore, one for each fork: sem_t forks[5].

```
void getforks() {
    sem_wait(forks[left(p)]);
    sem_wait(forks[right(p)]);

void putforks() {
    sem_post(forks[left(p)]);
    sem_post(forks[right(p)]);
    sem_post(forks[right(p)]);
}
```

The getforks() and putforks() Routines (Broken Solution)

- Deadlock occur!
 - If each philosopher happens to **grab the fork on their left** before any philosopher can grab the fork on their right.
 - Each will be stuck *holding one fork* and waiting for another, *forever*.

A Solution: Breaking The Dependency

- Change how forks are acquired.
 - Let's assume that philosopher 4 acquire the forks in a different order.

```
1  void getforks() {
2    if (p == 4) {
3         sem_wait(forks[right(p)]);
4         sem_wait(forks[left(p)]);
5    } else {
6         sem_wait(forks[left(p)]);
7         sem_wait(forks[right(p)]);
8    }
9  }
```

• There is no situation where each philosopher grabs one fork and is stuck waiting for another. **The cycle of waiting is broken**.

Using C.V. and locks to implement semaphore: Zemaphores

```
typedef struct Zem t {
      int value;
3
      pthread cond t cond;
      pthread mutex t lock;
4
   } Zem t;
6
   // only one thread can call this
   void Zem init(Zem t *s, int value) {
9
      s->value = value;
10
  Cond init(&s->cond);
11
  Mutex init(&s->lock);
12 }
```

Using C.V. and locks to implement semaphore: Zemaphores

```
1 void Zem_wait(Zem_t *s) {
2     Mutex_lock(&s->lock);
3     while (s->value <= 0)
4     Cond_wait(&s->cond, &s->lock);
5     s->value--;
6     Mutex_unlock(&s->lock);
7 }
```

Using C.V. and locks to implement semaphore: Zemaphores

```
22 void Zem_post(Zem_t *s) {
23    Mutex_lock(&s->lock);
24    s->value++;
25    Cond_signal(&s->cond);
26    Mutex_unlock(&s->lock);
27 }
```

- Zemaphore don't maintain the invariant that the value of the semaphore,
 when negative, reflects the number of waiting threads
 - The value never be lower than zero.
 - This behavior is **easier** to implement and **matches** the current Linux implementation.

Using semaphores to implement C.V.

- It's much more difficult!
 - Try it yourself
